

Design of air supply for generator room

How do you design a generator room?

The ventilation system and overall layout of a generator room should be examined in detail during the design process. While a generator set is specified by the electrical engineer, the onus is on the mechanical engineer for an optimum design that maximizes the performance, longevity, and reliability of the genset.

Does air supply mode affect the ventilation performance of a generator hall?

The air distribution and ventilation performance of the generator hall are influenced by the air supply mode [21]. To investigate the ventilation performance under various schemes, the velocity nonuniformity coefficient, temperature nonuniformity coefficient, and energy efficiency coefficient were selected as the evaluation indices in this study.

Why should a generator room be ventilated?

Proper ventilation of the generator room is necessary to support the engine combustion process, reject the parasitic heat generated during operation (engine heat, alternator heat, etc.), and purge odors and fumes.

What makes a good generator room?

A well-designed generator room will ensure that: Recirculation and bypass airflow is minimized; noise and vibration within and outside the building complies with code requirements, and ancillary components external to the generator set operate reliably.

Where should exhaust air be sourced for a generator?

For generators with remote radiators, it is recommended that the exhaust air should be sourced as high as possible and directly above the generator sets. Significant bypass of ventilation airflow directly into the discharge airflow will lead to reduction in cooling effectiveness and elevated temperatures within the room.

What makes a good engine room ventilation system?

The primary aspects of a properly designed engine room ventilation system are cooling air and combustion air. Cooling air refers to the flow of air that removes radiant heat from the engine, generator, other driven equipment and other engine room components. Combustion air describes the air the engine requires to burn fuel.

Design of the Generator Room. Ventilation: Ensure that the generator room has adequate ventilation to dissipate the heat generated during operation. ... Installing exhaust fans or air vents is necessary. Noise Control: Generators can be ...
