

How long are the blades of a large wind turbine

How many blades does a wind turbine have?

Most turbines have three blades which are made mostly of fiberglass. Turbine blades vary in size, but a typical modern land-based wind turbine has blades of over 170 feet (52 meters). The largest turbine is GE's Haliade-X offshore wind turbine, with blades 351 feet long (107 meters) - about the same length as a football field.

How long is a wind turbine rotor?

Wind turbine blade length or wind turbine blades size usually ranges from 18 to 107 meters (59 to 351 feet) long. Depending upon the use of the electricity produced. A large, utility-scale turbine may have blades over 165 feet (50 meters) long, thus the diameter of the rotor is over 325 feet (100 meters)

Why do turbines have longer blades?

Turbines with longer blades cover a larger area, allowing them to collect more wind and generate more power. The relationship between blade size and energy is exponential, meaning that doubling the blade length increases the power capacity by a factor of four.

What are wind turbine blades made of?

Forty years ago, wind turbine blades were only 26 feet long and made of fiberglass and resin. Today, blades can be 351 feet, longer than the height of the Statue of Liberty, and produce 15,000 kW of power. Modern blades are made from carbon-fiber and can withstand more stress due to higher strength properties.

What is a typical wind turbine size?

For homeowners curious about wind technology, understanding typical wind turbine sizes can be helpful. According to The United States Department of Energy, most modern land-based wind turbines have blades of over 170 feet (52 meters). This means that their total rotor diameter is longer than a football field.

What is the average rotor diameter of a wind turbine?

In 2023, the average rotor diameter of newly-installed wind turbines was over 133.8 meters (~438 feet)--longer than a football field, or about as tall as the Great Pyramid of Giza. Larger rotor diameters allow wind turbines to sweep more area, capture more wind, and produce more electricity.

The length of a wind turbine's blades directly affects its wind-swept area, which is the total planar area covered by the rotor. Turbines with longer blades cover a larger area, allowing them to collect more wind and generate more power.
