

Should solar power be stored?

Voltage and frequency control are provided by the generator; transient control is achieved by the storage. From the cost perspective, a new, controllable generator seems to be suitable, but in that case, curtailment of solar power remains. Storage can offer the possibility of avoiding curtailment.

Should a biogas turbine be installed in the island mode?

The generator shall ensure the control of the island mode operation. Using a generator means cost-efficiency as well. If 100% renewable share is the primary objective, it is worth analyzing the possibility of installing a biogas turbine.

How much power does a single solar PV array produce?

The anticipated generation capacity of the single solar PV array is around 0.044 kW, while the measured power production in the morning at 10.00 am is approximately 0.040 kW, as shown in Fig. 13 (a). For a single PV array, the GLD forecast error is around 0.004 kW.

Can a storage system sustain the available battery capacity?

The converter of the storage system shall be able to ensure island mode operation (converter with grid-forming capability), so the storage system takes over control tasks. Based on the NPV calculations, the proposal is to sustain the available battery capacity and its increase is suggested only if CAPEX technology is significantly reduced.

Thus, the objective of this work is to study the possibility of operating the island network in 2020 with only renewable generation and a BESS, analysing the system stability. ... this study aims obtaining the optimum capacities of ...
