

Creating the photovoltaic system diagram represents an important phase in relation to assessing your solar PV system production levels. It's fundamental to be able to size all system components as it affects the productivity and efficiency of the entire system.

A photovoltaic system is characterized by various fundamental elements: accumulators. The photovoltaic generator is the set of solar panels and is the element that converts solar energy into electricity.

Provide an architectural drawing and riser diagram for the homeowner showing the planned location for future photovoltaic and solar hot water system components. Space requirements and layout for photovoltaic and solar water heating system components should be taken into account early in the design process.

A stand-alone system has an additional device, the charge controller, which controls the charging or discharging process safeguarding battery life during the various phases. In these cases, using a photovoltaic system design software will allow you to size and configure the storage system by defining the type of battery and meter.

Solar photovoltaic modules are where the electricity gets generated, but are only one of the many parts in a complete photovoltaic (PV) system. In order for the generated electricity to be useful in a home or business, a number of other technologies must be in place.

The interface device is generally installed in a switchpanel and detects the electrical voltage: in the absence of a measurable voltage, it disconnects the photovoltaic generator from the rest of the system. There are two types of Photovoltaic systems: stand alone systems.
