

Stall type wind turbine generator

How to control dynamic stall in a wind turbine?

In addition to vortex generators, several other means have been proposed in literature to control dynamic stall (particularly for wind turbine applications), including constant blowing air jets [29, 30], periodic suction/blowing [, ,], leading edge suction , or plasma actuators [, ,].

How do you stall a wind turbine?

You can use pitch adjustment to stall and furl, two methods of pitch control. By stalling a wind turbine, you increase the angle of attack, which causes the flat side of the blade to face further into the wind. Furling decreases the angle of attack, causing the edge of the blade to face the oncoming wind.

Can vortex generators control dynamic stall?

The effect of vortex generators to control dynamic stall is investigated. A pitching airfoil for vertical-axis wind turbines is tested in the wind tunnel. Pressure measurements are made in steady and unsteady flow conditions. Vortex generators can suppress dynamic stall depending on the VG configuration.

Do passive VGS control the dynamic stall of wind turbine airfoil?

This favorably leads to 57% and 39% decreases in the hysteresis intensities of lift and pitching moment coefficients, respectively. These findings suggest that passive VGs are highly promising in controlling the dynamic stall of the wind turbine airfoil. 1. Introduction

How are wind turbines classified?

Usually wind turbines are classified by their mechanical power control, and further by their speed control. All turbine blades convert the motion of air across the air foils to torque and then regulate that torque in an attempt to capture as much energy as possible. Further wind turbines may be regulated or pitch regulated.

What control methods are used in wind turbines?

Pitch, yaw, and rotational speed control were the main control methods used to optimize or limit the power extracted from the wind. Wind-turbine control is essential for optimal performance, safe operation, and structural stability. This article appears courtesy of NI.

We use particle image velocimetry (PIV) experiments to investigate dynamic stall on vertical axis wind turbine blades in an effort to determine the correct scaling for the growth of the leading edge vortex, and the effect of tip speed ratio and ...
